

Ricci curvatures in Carnot groups

L. Rifford*

February 5, 2013

Abstract

We study metric contraction properties for metric spaces associated with left-invariant sub-Riemannian metrics on Carnot groups. We show that ideal sub-Riemannian structures on Carnot groups satisfy such properties and give a lower bound of possible curvature exponents in terms of the datas.

1 Introduction

Several notions of Ricci curvature (bounded from below) on measured metric spaces have been defined recently [19, 23, 25, 26]. The Ohta measure contraction property [23] reflects the way the volume of balls is distorted along geodesics. In [15], Juillet proved that Heisenberg groups equipped with their canonical sub-Riemannian metric and the Haar measure satisfy some measure contraction properties. The aim of the present paper is to extend Juillet's results to more general Carnot groups. In order to introduce Ohta's measure contraction property, we first study the Riemannian case. We refer the reader to the textbook [11] for further details in Riemannian geometry.

Let (M, g) be a complete smooth Riemannian manifold of dimension n , we denote by d_g the geodesic distance on M , by $dvol_g$ the canonical measure of (M, g) and by $\exp_x : T_x M \rightarrow M$ the exponential map from a point $x \in M$. Given $x \in M$, the cut locus of x , denoted by $\text{cut}(x)$, is the smallest closed set in M such that the pointed distance $y \in M \mapsto d_g(x, y)$ is smooth on its complement in M . That set can also be viewed as the closure of the set of points $y \in M$ such that at least two distinct minimizing geodesics join x to y . For every $y \in M \setminus \text{cut}(x)$, there is a unique minimizing geodesic joining x to y ; we denote by $v_y \in T_x M$ the tangent vector such that $\exp_x(v_y) = y$ and

*Université de Nice-Sophia Antipolis, Labo. J.-A. Dieudonné, UMR CNRS 6621, Parc Valrose, 06108 Nice Cedex 02, France (Ludovic.Rifford@math.cnrs.fr)

by $\gamma_{x,v_y} : [0, 1] \rightarrow M$ the geodesic starting at x with velocity v_y . The tangent injectivity locus at x is the subset of $T_x M$ defined as

$$\text{TIL}(x) := \left\{ v_y \mid y \in M \setminus \text{cut}(x) \right\};$$

it is an open subset of $T_x M$ which is star-shaped with respect to the origin and has a locally Lipschitz boundary [9, 14, 18]. Moreover, the mapping

$$\exp_x : \text{TIL}(x) \longrightarrow M \setminus \text{cut}(x)$$

is a smooth diffeomorphism. The set $\text{cut}(x)$ is the image of $\partial \text{TIL}(x)$ through \exp_x , hence it has measure zero. Let $x \in M$ and $A \subset M$ a measurable set with $0 < \text{vol}_g(A) < \infty$ be fixed. For every $s \in [0, 1]$, we call s -interpolation of A from x , the subset of M defined by

$$A_s := \left\{ \gamma_{x,v}(s) \mid v \in \text{TIL}(x), \exp_x(v) \in A \right\}.$$

Figure 1

Note that $A_0 = \{x\}$ while $A_1 = A \setminus \text{cut}(x)$. Denote by $U_x M$ the unit sphere in $(T_x M, g_x)$, and for every $s \in [0, 1]$ by D_s the subset of $T_x M$ corresponding to A_s through the exponential mapping in polar coordinates, that is

$$D_s := \left\{ (t, u) \in [0, +\infty) \times U_x M \mid \exp_x(tu) \in A_s \right\}.$$

Let $u \in U_x M$ and (e_1, \dots, e_n) be an orthonormal basis of $T_x M$ with $e_1 = u$. For every $t \geq 0$ let $\gamma_{x,u}(t) = \exp_x(tu)$, and let $(e_1(t), \dots, e_n(t))$ be an orthonormal basis of $T_{\gamma_{x,u}(t)} M$ obtained by parallel transport of (e_1, \dots, e_n) along $\gamma_{x,u}$. Let further, for $t \geq 0$,

$$R_{ij}(t, u) = \left\langle \text{Riem}_{\gamma_{x,u}(t)}(\dot{\gamma}_{x,u}(t), e_i(t)) \dot{\gamma}_{x,u}(t), e_j(t) \right\rangle_{\gamma_{x,u}(t)}, \quad 1 \leq i, j \leq n,$$

where Riem stands for the Riemann curvature tensor. Note that the $n \times n$ matrix $R(t, u) = (R_{ij}(t, u))$ is symmetric and satisfies $R_{i1}(t, u) = R_{1i}(t, u) = 0$ for any i . We

define $J(t, u)$, implicitly depending on x and (e_1, \dots, e_n) , as the matrix-valued solution of

$$\begin{cases} \ddot{J}(t, u) + R(t, u)J(t, u) = 0, \\ J(0, u) = 0_n, \quad \dot{J}(0, u) = I_n. \end{cases}$$

The first line and row of J always satisfy $J_{i1}(t, u) = J_{1i}(t, u) = t\delta_{i1}$ for any $t \geq 0$ and any i . Then the $(n-1) \times (n-1)$ block in the lower right of J , that we denote by \hat{J} , is solution to

$$\begin{cases} \ddot{\hat{J}}_i(t, u) + \hat{R}(t, u)\hat{J}_i(t, u) = 0, \\ \hat{J}(0, u) = 0_{n-1}, \quad \dot{\hat{J}}(0, u) = I_{n-1}, \end{cases} \quad (1.1)$$

where $\hat{R}(t, u)$ denotes the $(n-1) \times (n-1)$ block in the lower right of $R(t, u)$. Note that $\hat{J}(t, u)$ may depend on the orthonormal basis (e_1, \dots, e_n) of $T_x M$, however its determinant does not. Then we set

$$D(t, u) := \det(\hat{J}(t, u)) \quad \forall t \geq 0, \forall u \in U_x M, \quad (1.2)$$

which depends implicitly on x . Since $t^{-(n-1)}D(t, u)$ corresponds to the Jacobian determinant of the mapping $(t, u) \mapsto \exp_x(tu)$, we get by change of variable

$$\text{vol}_g(A) := \int_A 1 \, d\text{vol}_g(z) = \int_{A_1} 1 \, d\text{vol}_g(z) = \int_{D_1} D(t, u) \, dt \, du,$$

and for every $s \in [0, 1]$,

$$\text{vol}_g(A_s) = \int_{A_s} 1 \, d\text{vol}_g(z) = \int_{D_s} D(t, u) \, dt \, du = \int_{D_1} sD(st, u) \, dt \, du. \quad (1.3)$$

In the above change of variable, we used that for every $u \in U_x M$, the determinant of the Jacobi matrix $J(t, u)$ (or equivalently of $\hat{J}(t, u)$) is positive as long as the tangent vector tu (with $t > 0$) belongs to $\text{TIL}(x)$. For every $u \in U_x M$, we denote by $t_{\text{cut}}(u)$ the first time $t \geq 0$ such that $tu \notin \text{TIL}(x)$ (if tu always belongs to $\text{TIL}(x)$ we set $t_{\text{cut}}(u) = +\infty$). Given $u \in U_x M$, remembering (1.1) and that R (and a fortiori \hat{R}) is symmetric, we check easily that the $(n-1) \times (n-1)$ matrix

$$U(t, u) := \dot{\hat{J}}(t, u)\hat{J}(t, u)^{-1} \quad \forall t \in (0, t_{\text{cut}}(u))$$

satisfies the Riccati equation

$$\dot{U}(t, u) + U(t, u)^2 + \hat{R}(t, u) = 0 \quad \forall t \in (0, t_{\text{cut}}(u)), \quad (1.4)$$

and is symmetric. Since the derivative of a determinant is a trace, we have

$$\frac{\dot{D}(t, u)}{D(t, u)} = \operatorname{tr}(U(t, u)) \quad \forall t \in (0, t_{\text{cut}}(u)).$$

Moreover, the Cauchy-Schwarz inequality yields

$$(\operatorname{tr}(U(t, u)))^2 \leq \operatorname{tr}(U(t, u)^2) (n - 1).$$

Then taking the trace of (1.4), we get

$$\operatorname{tr}(\dot{U}(t, u)) + \frac{1}{n-1} [\operatorname{tr}(U(t, u))]^2 + \operatorname{tr}(\hat{R}(t, u)) \leq 0 \quad \forall t \in (0, t_{\text{cut}}(u)).$$

Recall that we have by definition of the Ricci curvature as a quadratic form

$$\operatorname{Ric}_g(\dot{\gamma}_{x,u}(t)) = \operatorname{tr}(\hat{R}(t, u)) \quad \forall t \in (0, t_{\text{cut}}(u)).$$

Therefore if a Riemannian manifold satisfies $\operatorname{Ric}_g \geq K$, we have

$$\frac{d}{dt} \left(\frac{\dot{D}(t, u)}{D(t, u)} \right) + \frac{1}{n-1} \left(\frac{\dot{D}(t, u)}{D(t, u)} \right)^2 + K \leq 0 \quad \forall t \in (0, t_{\text{cut}}(u)).$$

By classical comparison theorems, we infer that

$$\frac{\dot{D}(t, u)}{D(t, u)} \leq \sqrt{n-1} \frac{\dot{s}_K(t/\sqrt{n-1})}{s_K(t/\sqrt{n-1})} \quad \forall t \in (0, t_{\text{cut}}(u)), \quad (1.5)$$

where the function $s_K : [0, +\infty) \rightarrow [0, +\infty)$ ($s_K : [0, \pi/\sqrt{K}] \rightarrow [0, +\infty)$ if $K > 0$) is defined by

$$s_K(t) := \begin{cases} \frac{\sin(\sqrt{K}t)}{\sqrt{K}} & \text{if } K > 0 \\ t & \text{if } K = 0 \\ \frac{\sinh(\sqrt{-K}t)}{\sqrt{-K}} & \text{if } K < 0. \end{cases}$$

Then, for every $s \in (0, 1)$ integrating the inequality on $[st, t]$ yields (note that by Bonnet-Myers's Theorem, $K > 0$ implies $t_{\text{cut}}(u) < \pi\sqrt{n-1}/K$ for all u)

$$\frac{D(t, u)}{D(st, u)} \leq \left[\frac{s_K(t/\sqrt{n-1})}{s_K(st/\sqrt{n-1})} \right]^{n-1} \quad \forall t \in (0, t_{\text{cut}}(u)).$$

Then remembering (1.3), we get for every $s \in (0, 1)$,

$$\begin{aligned}
\text{vol}_g(A_s) &= \int_{D_1} sD(st, u) dt du \\
&\geq s \int_{D_1} \left[\frac{s_K(st/\sqrt{n-1})}{s_K(t/\sqrt{n-1})} \right]^{n-1} D(t, u) dt du \\
&= \int_{A_1} s \left[\frac{s_K(sd_g(x, z)/\sqrt{n-1})}{s_K(d_g(x, z)/\sqrt{n-1})} \right]^{n-1} d\text{vol}_g(z) \\
&= \int_A s \left[\frac{s_K(sd_g(x, z)/\sqrt{n-1})}{s_K(d_g(x, z)/\sqrt{n-1})} \right]^{n-1} d\text{vol}_g(z).
\end{aligned}$$

Note that the above inequality holds for $s = 0, 1$. Then summarizing we have the following result.

Proposition 1. *Let (M, g) be a complete smooth Riemannian manifold satisfying $\text{Ric}_g \geq K$. Then for every $x \in M$ and every measurable set $A \subset M$ with $0 < \text{vol}_g(A) < \infty$, we have*

$$\text{vol}_g(A_s) \geq \int_A s \left[\frac{s_K(sd_g(x, z)/\sqrt{n-1})}{s_K(d_g(x, z)/\sqrt{n-1})} \right]^{n-1} d\text{vol}_g(z) \quad \forall s \in [0, 1]. \quad (1.6)$$

According to the above result, Ohta introduced in [23] the notion of measure contraction property of general measured metric spaces that we proceed to define. For sake of simplicity we restrict our attention to measured metric spaces with negligible cut loci.

Definition 2. *Let (X, d, μ) be a measured metric space. We say that it is a geodesic space with negligible cut loci if for every $x \in X$, there is a measurable set $\mathcal{C}(x) \subset X$ with*

$$\mu(\mathcal{C}(x)) = 0,$$

and a measurable map $\mathcal{E}_x : (X \setminus \mathcal{C}(x)) \times [0, 1] \rightarrow X$ such that for every $y \in X \setminus \mathcal{C}(x)$ the curve

$$s \in [0, 1] \mapsto \mathcal{E}_x(y, s)$$

is the unique geodesic from x to y .

The following definition is equivalent to Ohta's definition [23, Definition 2.1] in the case of geodesic measured metric spaces with negligible cut loci.

Definition 3. Let (X, d, μ) be a measured metric space which is geodesic with negligible cut loci and $K \in \mathbb{R}, N > 1$ be fixed. We say that (X, d, μ) satisfies $\text{MCP}(K, N)$ if for every $x \in X$ and every measurable set $A \subset X$ (provided that $A \subset B_d(x, \pi\sqrt{N-1}/K)$ if $K > 0$) with $0 < \mu(A) < \infty$,

$$\mu(A_s) \geq \int_A s \left[\frac{s_K(sd(x, z)/\sqrt{N-1})}{s_K(d(x, z)/\sqrt{N-1})} \right]^{N-1} d\mu(z).$$

where A_s is the s -interpolation of A from x defined by

$$A_s := \left\{ \mathcal{E}_x(y, s) \mid y \in X \setminus \mathcal{C}(x) \right\} \quad \forall s \in [0, 1].$$

In particular, (X, d, μ) satisfies $\text{MCP}(0, N)$ if for every $x \in X$ and every measurable set A with $0 < \mu(A) < \infty$,

$$\mu(A_s) \geq s^N \mu(A) \quad \forall s \in [0, 1],$$

Of course, Euclidean spaces, that is \mathbb{R}^n equipped with a constant Riemannian metric, satisfy $\text{MCP}(0, n)$. Carnot groups are to sub-Riemannian geometry as Euclidean spaces are to Riemannian geometry. They are the metric tangent cones for this geometry. Elaborating on an idea of Gromov [13], Mitchell [21] proved that any sub-Riemannian structure does admit at generic points metric tangent cones which are Carnot groups equipped with left-invariant metrics. This property makes them prime candidates to satisfy $\text{MCP}(0, N)$. In [15], Juillet proved that the Heisenberg group \mathbb{H}_n equipped with its canonical sub-Riemannian metric and the Haar measure satisfies $\text{MCP}(0, N)$ with $N = 2n + 3$. Heisenberg groups are the most simple examples of sub-Riemannian structures. The aim of the present paper is to show the validity of Juillet's result for more general Carnot groups equipped with left-invariant sub-Riemannian structures and Haar measures. Let us now present briefly our results. We refer the reader to Section 2 for reminders in sub-Riemannian geometry and Carnot groups.

Theorem 4. Let \mathbb{G} be a Carnot group whose first layer is equipped with a left-invariant metric, assume that it is ideal. Then there is $N > 0$ such that the metric space (\mathbb{G}, d_{SR}) with Haar measure satisfies $\text{MCP}(0, N)$.

We call curvature exponent of a Carnot group \mathbb{G} whose first layer is equipped with a left-invariant metric the least $N \geq 1$ such that $\text{MCP}(0, N)$ is satisfied. The curvature exponent is ∞ if $\text{MCP}(0, N)$ is never satisfied for $N > 1$. Note that if N is finite, then \mathbb{G} (equipped with its sub-Riemannian structure) does satisfy $\text{MCP}(0, N)$.

Theorem 5. *Let \mathbb{G} be a Carnot group (equipped with a sub-Riemannian structure and the Haar measure), assume that it is a geodesic space with negligible cut loci. Then its curvature exponent N satisfies*

$$N \geq D + n - m,$$

where n is the topological dimension of \mathbb{G} , D its homogeneous dimension and m is the dimension of the first layer.

The paper is organized as follows. In Section 2, we recall some facts in sub-Riemannian geometry and Carnot groups theory. In particular, we recall important results regarding ideal sub-Riemannian structures. The proofs of Theorems 4 and 5 are given in Section 3. The last section contains comments.

2 Preliminaries

2.1 Sub-Riemannian structures

Let us first recall basic facts in sub-Riemannian geometry, we refer the reader to [2, 10, 22, 24] for further details. Let M be a smooth connected manifold without boundary of dimension $n \geq 3$, a sub-Riemannian structure on M is given by a pair (Δ, g) where Δ is a totally nonholonomic distribution with constant rank $m \in [2, n]$ on M and g is a smooth Riemannian metric on Δ . A path $\gamma : [0, 1] \rightarrow M$ is called horizontal if it belongs to $W^{1,2}([0, 1]; M)$ and satisfies

$$\dot{\gamma}(t) \in \Delta(\gamma(t)) \quad \text{a.e. } t \in [0, 1].$$

From the Chow-Rashevsky Theorem, any points $x, y \in M$ can be joined by an horizontal path. For every $x \in M$ and any $v \in \Delta(x)$, we denote by $|v|_x^g$ the norm of v with respect to the metric g . The length of an horizontal path $\gamma \in W^{1,2}([0, 1]; M)$ is defined as

$$\text{length}^g(\gamma) := \int_0^1 |\dot{\gamma}(t)|_{\gamma(t)}^g dt.$$

For every $x, y \in M$, the sub-Riemannian distance between x and y , denoted by $d_{SR}(x, y)$, is defined as the infimum of lengths of horizontal paths joining x to y , that is

$$d_{SR}(x, y) := \inf \left\{ \text{length}^g(\gamma) \mid \gamma \in W^{1,2}([0, 1]; M), \gamma(0) = x, \gamma(1) = y \right\}.$$

The function d_{SR} makes (M, d_{SR}) a metric space. The energy of an horizontal path $\gamma \in W^{1,2}([0, 1]; M)$ is defined as

$$\text{energy}^g(\gamma) := \int_0^1 \left(|\dot{\gamma}(t)|_{\gamma(t)}^g \right)^2 dt.$$

So the energy between x and y in M is defined as

$$e_{SR}(x, y) := \inf \left\{ \text{energy}^g(\gamma) \mid \gamma \in W^{1,2}([0, 1]; M), \gamma(0) = x, \gamma(1) = y \right\}.$$

The Cauchy-Schwarz inequality implies easily $e_{SR} = d_{SR}^2$ on $M \times M$. By the sub-Riemannian Hopf-Rinow Theorem, if (M, d_{SR}) is assumed to be complete, then for every $x, y \in M$ there exists at least one minimizing geodesic joining x to y , that is an horizontal path $\gamma : [0, 1] \rightarrow M$ with $\gamma(0) = x, \gamma(1) = y$ satisfying

$$d_{SR}(x, y) = \text{length}^g(\gamma) = \sqrt{\text{energy}^g(\gamma)}.$$

We need now to introduce the notion of singular horizontal curves. For sake of simplicity we restrict our attention to minimizing geodesic curves. Let $x, y \in M$ and a minimizing geodesic $\gamma \in W^{1,2}([0, 1]; M)$ joining x to y be fixed. Since γ minimizes the distance between x and y it cannot have self-intersection. Hence (Δ, g) admits an orthonormal frame along γ . There is an open neighborhood \mathcal{V} of $\gamma([0, 1])$ in M and an orthonormal family \mathcal{F} (with respect to g) of m smooth vector fields X^1, \dots, X^m such that

$$\Delta(z) = \text{Span} \left\{ X^1(z), \dots, X^m(z) \right\} \quad \forall z \in \mathcal{V}.$$

Moreover there is a control $u^\gamma \in L^2([0, 1]; \mathbb{R}^m)$ such that

$$\dot{\gamma}(t) = \sum_{i=1}^m u_i^\gamma(t) X^i(\gamma(t)) \quad \text{a.e. } t \in [0, 1].$$

The End-Point mapping from x is defined in an open neighborhood $\mathcal{U} \subset L^2([0, 1]; \mathbb{R}^m)$ of u^γ as

$$\begin{aligned} E_{\mathcal{F}}^{x,1} : \mathcal{U} &\longrightarrow M \\ u &\longmapsto \gamma_u(1), \end{aligned}$$

where γ_u is solution to the non-autonomous Cauchy problem

$$\dot{\gamma}_u(t) = \sum_{i=1}^m u_i(t) X^i(\gamma_u(t)) \quad \text{a.e. } t \in [0, 1], \quad \gamma_u(0) = x.$$

There is locally a one-to-one correspondence between the set of horizontal paths starting from x and the set of controls in $L^2([0, 1]; \mathbb{R}^m)$. The End-Point mapping $E_{\mathcal{F}}^{x,1}$ is smooth in \mathcal{U} .

Definition 6. *A minimizing geodesic γ is called singular if $E_{\mathcal{F}}^{x,1}$ is not a submersion at u^γ , that is if*

$$D_{u^\gamma} E_{\mathcal{F}}^{x,1} : L^2([0, 1]; \mathbb{R}^m) \longrightarrow T_{\gamma(1)} M$$

is not onto.

If γ is a minimizing geodesic between x and y which is not singular, then it is the projection of what one calls a normal extremal, that is a trajectory of the Hamiltonian system associated canonically with $H : T^*M \rightarrow \mathbb{R}$ defined by

$$H(x, p) := \frac{1}{2} \sum_{i=1}^m (p \cdot X^i(x))^2 \quad \forall (x, p) \in T^*M \simeq \mathcal{V} \times (\mathbb{R}^n)^*.$$

As a consequence any non-singular minimizing geodesic is smooth. (In the following definition, a geodesic is called non-trivial if it is not constant.)

Definition 7. *Let (Δ, g) be a sub-Riemannian structure of rank m on M . It is called ideal if it is complete and has no non-trivial singular minimizing geodesics.*

As explained in [24], ideal SR structures share the same properties as Riemannian manifolds outside the diagonal (the subset of $M \times M$ consisting of pairs (x, x) with $x \in M$). Given a sub-Riemannian structure on M and $x \in M$, we define the SR cut-locus at x as

$$\text{cut}_{SR}(x) := \overline{\Sigma(d_{SR}(x, \cdot))}, \quad (2.1)$$

where $\Sigma(d_{SR}(x, \cdot))$ denotes the set of $y \in M$ such that the pointed distance $d_{SR}(x, \cdot)$ is not differentiable at y .

Proposition 8. *Let (Δ, g) be an ideal sub-Riemannian structure on M . Then the following properties hold:*

- (i) *The sub-Riemannian distance d_{SR} is locally semiconcave outside the diagonal in $M \times M$, that is it can be written in local coordinates as the sum of a concave and a smooth function;*
- (ii) *for every $x \in M$, the set $\text{cut}_{SR}(x)$ has Lebesgue measure zero;*
- (iii) *for every $x \in M$, the set $\text{cut}_{SR}(x) \setminus \{x\}$ is exactly the closure of the set of $y \in M$ which can be joined to x with at least two minimizing geodesics;*
- (iv) *for every $x \in M$, the pointed distance $d_{SR}(x, \cdot)$ is smooth on $M \setminus \text{cut}_{SR}(x)$;*
- (v) *for every $y \in M \setminus \{x\}$ and every minimizing geodesic from x to y , we have*

$$\gamma(t) \notin \text{cut}_{SR}(x) \quad \forall t \in (0, 1).$$

The first example of ideal sub-Riemannian structure is given by the Heisenberg group or more generally by fat distributions (see Section 4.1).

2.2 Carnot groups

We recall here basic facts on Carnot groups. We refer the reader to [17] and references therein for further details. A Carnot group (\mathbb{G}, \star) of step s is a simply connected Lie group whose Lie algebra $\mathfrak{g} = T_0\mathbb{G}$ (we denote by 0 the identity element of \mathbb{G}) admits a nilpotent stratification of step s , *i.e.*

$$\mathfrak{g} = V_1 \oplus \cdots \oplus V_s, \quad (2.2)$$

with

$$[V_1, V_j] = V_{j+1} \quad \forall 1 \leq j \leq s, \quad V_s \neq \{0\}, \quad V_{s+1} = \{0\}. \quad (2.3)$$

We denote by m_j the dimension of each layer V_j and by

$$n = m_1 + \cdots + m_s, \quad (2.4)$$

the topological dimension of \mathbb{G} . Given $x \in \mathbb{G}$, the mapping $L_x : \mathbb{G} \rightarrow \mathbb{G}$ defined by

$$L_x(y) = x \star y \quad \forall y \in \mathbb{G},$$

denotes the left-translation by the element x . Every $v \in \mathfrak{g} = T_0\mathbb{G}$ gives rise to a left-invariant vector field X_v on \mathbb{G} defined by

$$X_v(x) := (L_x)_*(v) := d_0L_x(v) \quad \forall x \in \mathbb{G}.$$

The exponential map

$$\exp_{\mathbb{G}} : \mathfrak{g} \rightarrow \mathbb{G}$$

evaluated at $v \in \mathfrak{g}$ is given by $\gamma(1)$, where $\gamma : \mathbb{R} \rightarrow \mathbb{G}$ is solution to the Cauchy problem $\dot{\gamma} = X_v(\gamma)$, $\gamma(0) = 0$. By simple-connectedness of \mathbb{G} and nilpotency of \mathfrak{g} , $\exp_{\mathbb{G}}$ is a smooth diffeomorphism, which allows to identify \mathbb{G} with its Lie algebra $\mathfrak{g} \simeq \mathbb{R}^n$. Fix a vector basis v_1, \dots, v_n of \mathfrak{g} satisfying

$$\begin{cases} v_1, \dots, v_{m_1} \in V_1, \\ v_{m_1+1}, \dots, v_{m_1+m_2} \in V_2, \\ \vdots \\ v_{n-m_s+1}, \dots, v_n \in V_s. \end{cases}$$

The coordinates (x_1, \dots, x_n) are the exponential coordinates of $\exp_{\mathbb{G}}(\sum_{i=1}^n x_i v_i) \in \mathbb{G}$. The group law on \mathbb{G} can be pulled back into a group law on \mathbb{R}^n (that is still denoted by \star) by exponential coordinates,

$$x \star y = \exp_{\mathbb{G}}^{-1} \left(\exp_{\mathbb{G}} \left(\sum_{i=1}^n x_i v_i \right) \star \exp_{\mathbb{G}} \left(\sum_{i=1}^n y_i v_i \right) \right) \quad \forall x, y \in \mathbb{R}^n.$$

With such a group law \mathbb{R}^n is a Lie group whose Lie algebra is isomorphic to \mathfrak{g} , making (\mathbb{G}, \star) and (\mathbb{R}^n, \star) isomorphic. If $i \in \{1, \dots, n\}$ is an index such that

$$m_1 + \dots + m_{d_i-1} < i \leq m_1 + \dots + m_{d_i}$$

for some $d_i \in \{1, \dots, s\}$, the coordinate x_i will be said to have degree d_i . The family $\{\delta_\lambda\}_{\lambda>0}$ defined as

$$\delta_\lambda(x_1, \dots, x_n) = \left(\lambda^{d_1} x_1, \lambda^{d_2} x_2, \dots, \lambda^{d_n} x_n \right) \quad \forall x \in \mathbb{R}^n,$$

provides a one-parameter family of dilations in \mathbb{R}^n . We have

$$\delta_1 = \text{Id}_{\mathbb{R}^n} \quad \text{and} \quad \delta_{\lambda\lambda'} = \delta_\lambda \circ \delta_{\lambda'} \quad \forall \lambda, \lambda' > 0.$$

For every $i = 1, \dots, n$, denote by X^i the left-invariant vector field on \mathbb{R}^n , written as

$$X^i(x) = \sum_{k=1}^n a_{ki}(x) \partial_k,$$

such that $X^i(0) = \partial_i$. It can be checked that each X^i is homogeneous of degree d_i with respect to $\{\delta_\lambda\}_{\lambda>0}$, that is

$$a_{ki}(\delta_\lambda(x)) = \lambda^{d_k - d_i} a_{ki}(x) \quad \forall k = 1, \dots, n, \forall x \in \mathbb{R}^n.$$

In particular, each vector field X^1, \dots, X^{m_1} satisfies

$$X^i(\delta_\lambda(x)) = \lambda^{-1} \delta_\lambda(X^i(x)) \quad \forall x \in \mathbb{R}^n. \quad (2.5)$$

The quantity

$$D := \sum_{i=1}^n d_i = \sum_{j=1}^s j m_j$$

is called the homogeneous dimension of \mathbb{G} . The Haar measure of (\mathbb{R}^n, \star) is (up to a multiplicative constant) the Lebesgue measure \mathcal{L}^n . Any metric on the first layer provides a sub-Riemannian metric by translation, and subsequently gives a sub-Riemannian structure (Δ, g) (with $\Delta(x) = (L_x)_*(V_1)$ and $g_x = (L_x)_*(g)$) on \mathbb{G} . Denote by d_{SR} the sub-Riemannian distance for the left-invariant SR structure (Δ, g) . The metric space (\mathbb{G}, d_{SR}) is necessarily complete and we check easily that if $\gamma : [0, 1] \rightarrow \mathbb{G}$ is a minimizing geodesic from $x := \gamma(0)$ to $y := \gamma(1)$, then for every $z \in \mathbb{G}$, the horizontal path

$$t \in [0, 1] \longmapsto z \star \gamma(t)$$

is a minimizing geodesic from $z \star x$ to $z \star y$. In particular, the sub-Riemannian distance is invariant by left-translations,

$$d_{SR}(z \star x, z \star y) = d_{SR}(x, y) \quad \forall x, y, z \in \mathbb{G}.$$

If we pull-back everything in \mathbb{R}^n by exponential coordinates, then the homogeneity of the first layer (see (2.5)) implies that if $\gamma : [0, 1] \rightarrow \mathbb{G}$ is a minimizing geodesic from 0 to $x := \gamma(1)$, then for every $\lambda > 0$, the horizontal path $\delta_\lambda \circ \gamma$ is minimizing from 0 to x . Then we have

$$d_{SR}(0, \delta_\lambda(x)) = \lambda d_{SR}(0, x) \quad \forall x \in \mathbb{R}^n. \quad (2.6)$$

In particular, the homogeneity property of the SR distance yields the invariance of sub-Riemannian balls by dilations,

$$\delta_\lambda(B_{SR}(0, r)) = B_{SR}(0, \lambda r) \quad \forall \lambda, r > 0, \quad (2.7)$$

where $B_{SR}(0, \lambda)$ denotes the sub-Riemannian ball centered at the origin with radius λ .

2.3 Sub-Riemannian Euler-Arnold equations

In the spirit of Arnold [5], we can write the equations of geodesics in the Lie algebra \mathfrak{g} . Recall that $m_l =: m(l)$ denotes the dimension of each layer V_l . For each $l = 1, \dots, s$, we pick an orthonormal basis $e_1^l, \dots, e_{m_l}^l$ of V_l (remember (2.2)). Thus by (2.3), there are structure constants $(\alpha_{ij,k}^{1,l})$ such that

$$[e_i^1, e_j^l] = \sum_{k=1}^{m(l+1)} \alpha_{ij,k}^{1l} e_k^{l+1}. \quad (2.8)$$

For every $l = 1, \dots, s-1$ and every $k = 1, \dots, m(l+1)$ denote by A_k^{1l} the $m(l) \times m$ matrix whose the coefficients are given by

$$(A_k^{1l})_{ij} = \alpha_{ij,k}^{1l}. \quad (2.9)$$

For each i, l , we denote by X_i^l the left-invariant vector field on \mathbb{G} obtained from e_i^l . Let us now consider a minimizing geodesic $\gamma : [0, 1] \rightarrow \mathbb{G}$ starting at the origin. It is associated with a smooth control $u^\gamma : [0, 1] \rightarrow \mathbb{R}^m$ (note that $m_1 = m$) satisfying

$$\dot{\gamma}(t) = \sum_{i=1}^m u_i^\gamma(t) X_i^1(\gamma(t)) \quad \forall t \in [0, 1], \quad \gamma(0) = 0.$$

The following result follows easily from the Hamiltonian equation for SR geodesics.

Proposition 9. *The horizontal curve γ is the projection of a normal extremal if and only if there are s smooth functions*

$$h^1 : [0, 1] \rightarrow \mathbb{R}^{m_1}, \quad \dots, \quad h^s : [0, 1] \rightarrow \mathbb{R}^{m_s}$$

satisfying

$$\begin{cases} \dot{h}^l &= \sum_{k=1}^{m(l+1)} h_k^{l+1} A_k^{1l} h^1 \quad \forall l \in 1, \dots, s-1, \\ \dot{h}^s &= 0, \end{cases} \quad (2.10)$$

such that

$$u_i^\gamma(t) = h_i^1(t) \quad \forall i = 1, \dots, m, \quad \forall t \in [0, 1]. \quad (2.11)$$

Proof. Define in local coordinates along $\gamma([0, 1])$, the Hamiltonian $H : \mathcal{V} \times (\mathbb{R}^n)^* \rightarrow \mathbb{R}$ by

$$H(x, p) := \frac{1}{2} \sum_{i=1}^m (p \cdot X_i^1(x))^2 \quad (2.12)$$

for all $(x, p) \in \mathcal{V} \times (\mathbb{R}^n)^*$. Then there is a smooth arc $p : [0, 1] \rightarrow (\mathbb{R}^n)^*$ such that the pair (γ, p) satisfies

$$\begin{cases} \dot{\gamma}(t) &= \frac{\partial H}{\partial p}(\gamma(t), p(t)) = \sum_{i=1}^m [p(t) \cdot X_i^1(\gamma(t))] X^i(\gamma(t)) \\ \dot{p}(t) &= -\frac{\partial H}{\partial x}(\gamma(t), p(t)) = -\sum_{i=1}^m [p(t) \cdot X_i^1(\gamma(t))] p(t) \cdot d_{\gamma(t)} X_i^1 \end{cases} \quad (2.13)$$

for any $t \in [0, 1]$ and

$$u_i^\gamma(t) = p(t) \cdot X_i^1(\gamma(t)) \quad \forall t \in [0, 1], \quad \forall i = 1, \dots, m. \quad (2.14)$$

Setting $h_i^l := p(t) \cdot X_i^l(\gamma(t))$, we have (with the convention $[X, Y](x) = d_x X(Y(x)) - d_x Y(X(x))$)

$$\begin{aligned} \dot{h}_i^l(t) &= \dot{p}(t) \cdot X_i^l(\gamma(t)) + p(t) \cdot d_{\gamma(t)} X_i^l(\dot{\gamma}(t)) \\ &= -\sum_{j=1}^m h_j^1(t) p(t) \cdot d_{\gamma(t)} X_j^1 \left(X_i^l(\gamma(t)) \right) + p(t) \cdot d_{\gamma(t)} X_i^l \left(\sum_{j=1}^m h_j^1(t) X_j^1(\gamma(t)) \right) \\ &= \sum_{j=1}^m h_j^1(t) p(t) \cdot [X_i^1, X_j^1](\gamma(t)) = \sum_{j=1}^m h_j^1(t) p(t) \cdot [e_i^1, e_j^1]. \end{aligned}$$

We conclude by (2.8)-(2.9). □

Let us now pull back $\gamma_u : [0, 1] \rightarrow \mathbb{G}$ by the \mathbb{G} -exponential in order to obtain a curve $c_u : [0, 1] \rightarrow \mathfrak{g}$. Recall that for every $v \in \mathfrak{g}$, the family of linear maps $\{\text{ad}_v^k\}_{k \in \mathbb{N}} : \mathfrak{g} \rightarrow \mathfrak{g}$ is defined by

$$\text{ad}_v^0(w) = w, \quad \text{ad}_v^{k+1}(w) = \text{ad}_v^1(\text{ad}_v^k(w)) = [v, \text{ad}_v^k(w)] \quad \forall w \in \mathfrak{g}.$$

We have

Lemma 10. *The smooth curve $c_u : [0, 1] \rightarrow \mathfrak{g}$ satisfies*

$$\sum_{k=0}^{s-1} \frac{(-1)^k}{(k+1)!} \text{ad}_{c_u(t)}^k(\dot{c}_u(t)) = \sum_{i=1}^m h_i^1(t) e_i^1 \quad \forall t \in [0, 1]. \quad (2.15)$$

Proof. As a simply connected nilpotent Lie group, we may view \mathbb{G} as a closed subgroup of the group of upper triangular matrices of a certain size having 1's on the diagonal. In that case, the exponential is given by the usual exponential on matrices and the adjoint map is defined by $\text{ad}_A(B) = [A, B] = AB - BA$ for any A, B . Given two squared matrices A, B of the same size, we first show that

$$F(A, B) := \frac{d}{dt} \left\{ e^{-A} e^{A+tB} \right\}_{t=0} = e^{-A} \frac{d}{dt} \left\{ e^{A+tB} \right\}_{t=0} = \sum_{k=0}^{\infty} \frac{(-1)^k}{(k+1)!} \text{ad}_A^k(B). \quad (2.16)$$

As a matter of fact, on the one hand we have

$$\begin{aligned}
F(A, B) &= \left(\sum_{k=0}^{\infty} \frac{(-1)^k}{k!} A^k \right) \left(\sum_{l=1}^{\infty} \frac{1}{l!} \frac{d}{dt} \left\{ (A + tB)^l \right\}_{t=0} \right) \\
&= \left(\sum_{k=0}^{\infty} \frac{(-1)^k}{k!} A^k \right) \left(\sum_{l=1}^{\infty} \frac{1}{l!} \sum_{q=1}^l A^{l-q} B A^{q-1} \right) \\
&= \left(\sum_{k=0}^{\infty} \frac{(-1)^k}{k!} A^k \right) \left(\sum_{l=0}^{\infty} \sum_{r=0}^l \frac{1}{(l+1)!} A^{l-r} B A^r \right) \\
&= \sum_{k=0}^{\infty} \sum_{l=0}^{\infty} \sum_{s=0}^l \frac{(-1)^k}{k!(l+1)!} A^k A^s B A^{l-s} \\
&= \sum_{k=0}^{\infty} \sum_{s=0}^{\infty} \sum_{j=k+s}^{\infty} \frac{(-1)^k}{k!(j+1-k)!} A^{k+s} B A^{j-k-s} \\
&= \sum_{j=0}^{\infty} \sum_{i=0}^j \sum_{r=0}^i \frac{(-1)^r}{(j+1)!} \binom{j+1}{r} A^i B A^{j-i} \\
&= \sum_{j=0}^{\infty} \sum_{i=0}^j \frac{1}{(j+1)!} \left(\sum_{r=0}^i (-1)^r \binom{j+1}{r} \right) A^i B A^{j-i} \\
&= \sum_{j=0}^{\infty} \sum_{i=0}^j \frac{1}{(j+1)!} \left((-1)^i \binom{j}{i} \right) A^i B A^{j-i} \\
&= \sum_{j=0}^{\infty} \frac{(-1)^j}{(j+1)!} \left(\sum_{i=0}^j \binom{j}{i} (-1)^{j-i} A^i B A^{j-i} \right), \tag{2.17}
\end{aligned}$$

where we used the identity

$$\sum_{r=0}^i (-1)^r \binom{j+1}{r} = (-1)^i \binom{j}{i}.$$

On the other hand, the binomial theorem yields

$$\text{ad}_A^k(B) = \sum_{r=0}^k \binom{k}{r} (-1)^{k-r} A^r B A^{k-r}.$$

Then the identity (2.16) follows from the above formula and (2.17). By construction,

the path $c_u : [0, 1] \rightarrow \mathbb{G}$ satisfies for every $t \in [0, 1]$,

$$d_{c_u(t)} \exp_{\mathbb{G}}(\dot{c}_u(t)) = \dot{\gamma}_u(t) = \sum_{i=1}^m u_i(t) X_i^1(\gamma_u(t)),$$

which yields

$$\begin{aligned} d_{\gamma_u(t)} L_{\gamma_u(t)^{-1}} \left(d_{c_u(t)} \exp_{\mathbb{G}}(\dot{c}_u(t)) \right) &= d_{\gamma_u(t)} L_{\gamma_u(t)^{-1}} \left(\sum_{i=1}^m u_i(t) X_i^1(\gamma_u(t)) \right) \\ &= \sum_{i=1}^m h_i^1(t) e_i^1. \end{aligned} \quad (2.18)$$

But there holds for every $t \in [0, 1]$,

$$\begin{aligned} \frac{d}{ds} \left\{ \exp_{\mathbb{G}}(-\gamma_u(t)) \star \exp_{\mathbb{G}}(c_u(t+s)) \right\}_{s=0} &= \frac{d}{ds} \left\{ L_{\gamma_u(t)^{-1}} \left(\exp_{\mathbb{G}}(c_u(t+s)) \right) \right\}_{s=0} \\ &= d_{\gamma_u(t)} L_{\gamma_u(t)^{-1}} \left(d_{c_u(t)} \exp_{\mathbb{G}}(\dot{c}_u(t)) \right). \end{aligned}$$

We conclude by (2.16), (2.18) and the fact that \mathbb{G} is nilpotent of step s . \square

3 Proof of the results

3.1 Proof of Theorem 4

Up to pulling-back the metric to \mathbb{R}^n by the exponential map $\exp_{\mathbb{G}}$, we can assume that our Carnot group is (\mathbb{R}^n, \star) equipped with a left-invariant metric g and with the Lebesgue measure \mathcal{L}^n as Haar measure. We need to show that there is $N > 0$ such that for every measurable set A with $0 < \mathcal{L}^n(A) < \infty$,

$$\text{vol}_{\mathbb{G}}(A_s) \geq s^N \text{vol}_{\mathbb{G}}(A) \quad \forall s \in [0, 1]. \quad (3.1)$$

Note that since the sub-Riemannian structure is invariant by translation, it is sufficient to prove the result for $x = 0$. Let us now assume that the sub-Riemannian structure on \mathbb{G} is ideal.

Lemma 11. *There is $N > 0$ such that for every measurable set $A \subset B_{SR}(0, 1) \setminus B_{SR}(0, 1/2)$, we have*

$$\text{vol}_{\mathbb{G}}(A_s) \geq s^N \text{vol}_{\mathbb{G}}(A) \quad \forall s \in [1/2, 1]. \quad (3.2)$$

Proof of Lemma 11. By Proposition 8, the pointed distance function $f : x \mapsto d_{SR}(0, x)$ is locally semiconcave outside the origin and smooth outside $\text{cut}_{SR}(0)$. Then there is a constant $K > 0$ (see [8]) such that

$$\text{Hess}_x f \leq KI_n, \quad (3.3)$$

for every x in the open set $\Omega := (\mathbb{R}^n \setminus \text{cut}_{SR}(0)) \cap (B_{SR}(0, 1) \setminus B_{SR}(0, 1/4))$ (here Hess denotes the canonical Hessian in \mathbb{R}^n). Denote by $Z : \Omega \rightarrow \mathbb{R}^n$ the optimal synthesis associated with $f = d_{SR}(0, \cdot)$, that is the smooth vector field defined by

$$Z(x) := -\mathcal{P}_{\Delta(x)}(d_x f) \quad \forall x \in \Omega, \quad (3.4)$$

where $\mathcal{P}_{\Delta(x)} : (\mathbb{R}^n)^* \rightarrow \mathbb{R}^n$ denotes the projection to $\Delta(x)$ which is defined by

$$\mathcal{P}_{\Delta(x)}(p) := v \in \Delta(x) \text{ such that } p \cdot w = g(v, w) \forall w \in \Delta(x).$$

Note that since $f = d_{SR}(0, \cdot)$ is solution to the horizontal eikonal equation

$$H(x, d_x f) = \frac{1}{2} \quad \forall x \in \mathbb{R}^n \setminus \{0\},$$

the vector field Z has always norm 1 with respect to g . We denote by ϕ_t^Z the flow of Z . Set $\mathcal{A} := B_{SR}(0, 1) \setminus B_{SR}(0, 1/2)$ and fix a measurable set $A \subset \mathcal{A}$. Note that

$$A_s = \phi_{1-s}^Z(A_1) \subset \Omega \quad \forall s \in [1/2, 1].$$

Then we have by definition of the divergence,

$$\frac{d}{dt} \left\{ \mathcal{L}^n(\phi_t^Z(A_1)) \right\} = \int_{\phi_t^Z(A_1)} \text{div}_x Z \, dx \quad \forall t \in (0, 1/2].$$

Then writing (3.4) as $Z(x) = -G(x, d_x f)$ and setting $G^p := G(\cdot, p)$, $G^x := G(x, \cdot)$, we have (note that G^x is linear)

$$\text{div}_x Z = \sum_{i=1}^n \frac{\partial Z_i}{\partial x_i}(x) = -\text{div}_x G^{d_x f} - \text{tr}(G^x \circ \text{Hess}_x f) \quad \forall x \in \Omega.$$

The first term in the above formula is bounded (f is Lipschitz on Ω and G is smooth) and by (3.3) the second term is bounded from below (G^x is a linear projection). This shows that there is $C > 0$ such that for every $t \in (0, 1/2]$,

$$\frac{d}{dt} \left\{ \mathcal{L}^n(A_{1-t}) \right\} = \frac{d}{dt} \left\{ \mathcal{L}^n(\phi_t^X(A_1)) \right\} \geq \int_{\phi_t^X(A_1)} -C \, dz \geq -C \mathcal{L}^n(A_{1-t}).$$

By Gronwall's Lemma, we infer that for every $s \in [1/2, 1)$,

$$\mathcal{L}^n(A_s) \geq e^{C(s-1)} \mathcal{L}^n(A_1).$$

We conclude easily. □

Lemma 12. *There is $N > 0$ such that for every $k \in \mathbb{Z}$ and every measurable set*

$$A \subset B_{SR} \left(0, \frac{1}{2^k} \right) \setminus B_{SR} \left(0, \frac{1}{2^{k+1}} \right), \quad (3.5)$$

we have

$$\text{vol}_{\mathbb{G}}(A_s) \geq s^N \text{vol}_{\mathbb{G}}(A) \quad \forall s \in [0, 1]. \quad (3.6)$$

Proof of Lemma 12. Recall that for every $\lambda > 0$, δ_λ denotes the dilations in \mathbb{R}^n of ratio λ . By dilations properties (2.6)-(2.7), for every integer k and every measurable set A satisfying (3.5), we have

$$\delta_{2^k}(A) \subset B_{SR}(0, 1) \setminus B_{SR}(0, 1/2) \quad \text{and} \quad \delta_{2^k}(A_s) = (\delta_{2^k}(A))_s \quad \forall s \in [0, 1].$$

As a consequence, it is sufficient to prove (3.6) with a measurable set A satisfying (3.5) with $k = 0$. Note that for every $s \in (0, 1/2)$, $A_s = (A_{2s})_{1/2}$. Given $s \in (1/4, 1/2)$, we denote by $\delta_{(2s)^{-1}}$ the dilation of ratio $1/(2s)$ and we set

$$B := \delta_{(2s)^{-1}}(A_{2s}) \subset B_{SR}(0, 1) \setminus B_{SR}(0, 1/2).$$

By dilation properties (see (2.6)), $B_{1/2} = \delta_{(2s)^{-1}}(A_s)$. Then using (3.2), we get (recall that D denotes the homogeneous dimension)

$$(2s)^{-D} \text{vol}_{\mathbb{G}}(A_s) = \text{vol}_{\mathbb{G}}(B_{1/2}) \geq \frac{1}{2^N} \text{vol}_{\mathbb{G}}(B) = \frac{(2s)^{-D}}{2^N} \text{vol}_{\mathbb{G}}(A_{2s}).$$

Thus we obtain recursively (we set $\kappa := 2^{-N}$)

$$\text{vol}(A_{1/2^l}) \geq \kappa^l \text{vol}(A).$$

Which implies for every $s \in [0, 1]$ with $2^l s \in [1/2, 1]$ (again using (3.2)),

$$\text{vol}_{\mathbb{G}}(A_s) = \text{vol}_{\mathbb{G}} \left((A_{2^l s})_{1/2^l} \right) \geq \kappa^l \text{vol}_{\mathbb{G}}(A_{2^l s}) \geq \kappa^l 2^{lN} s^N \text{vol}_{\mathbb{G}}(A) = s^N \text{vol}_{\mathbb{G}}(A).$$

This concludes the proof. □

We conclude easily the proof of the ideal case by decomposing any measurable set $A \subset \mathbb{R}^n$ with $0 < \mathcal{L}^n(A) < \infty$ as

$$A = \bigcup_{k \in \mathbb{Z}} A^k \quad \text{with} \quad A^k := A \cup \left(B_{SR} \left(0, \frac{1}{2^k} \right) \setminus B_{SR} \left(0, \frac{1}{2^{k+1}} \right) \right)$$

and applying Lemma 12.

3.2 Proof of Theorem 5

For every $h \in \mathbb{R}^n$, the solution $h = h_h : [0, 1] \rightarrow \mathbb{R}^n$ of the system (2.10) starting at h gives the control law $u = u_h : [0, 1] \rightarrow \mathbb{R}^m$ of the normal extremal starting at the origin with covector $p = \sum_{i=1}^n h_i dv_i$ (where dv_1, \dots, dv_n denotes the dual basis of v_1, \dots, v_n). Recall that the pull back of the corresponding geodesic, which is denoted by $c = c_h : [0, 1] \rightarrow \mathfrak{g}$ satisfies (see (2.15))

$$\sum_{k=0}^{s-1} \frac{(-1)^k}{(k+1)!} \text{ad}_{c(t)}^k (\dot{c}(t)) = \sum_{i=1}^m h_i(t) e_i^1 \quad \forall t \in [0, 1]. \quad (3.7)$$

For every integer $l \geq 0$, we denote by $c^{(l)}(0)$ the l -th derivative of c at $t = 0$ and we set $V_l = \{0\}$ for $l \geq s + 1$.

Lemma 13. *For every $h \in \mathbb{R}^n$,*

$$\dot{c}(0) \in V_1 \quad \text{and} \quad c^{(l)}(0) \in V_1 \oplus \dots \oplus V_{l-1} \quad \forall l \geq 2.$$

Proof of Lemma 13. By bilinearity of the Lie bracket in \mathfrak{g} and the binomial theorem, we check easily that for every integer $k \geq 0$, and for every integer $l \geq 1$,

$$\begin{aligned} \frac{d^l}{dt^l} \left\{ \text{ad}_{c(t)}^{k+1} (\dot{c}(t)) \right\}_{t=0} &= \frac{d^l}{dt^l} \left\{ [c(t), \text{ad}_{c(t)}^k (\dot{c}(t))] \right\}_{t=0} \\ &= \sum_{r=0}^l \binom{l}{r} \left[c^{(l-r)}(0), \frac{d^r}{dt^r} \left\{ \text{ad}_{c(t)}^k (\dot{c}(t)) \right\}_{t=0} \right] \\ &= \sum_{r=0}^{l-1} \binom{l}{r} \left[c^{(l-r)}(0), \frac{d^r}{dt^r} \left\{ \text{ad}_{c(t)}^k (\dot{c}(t)) \right\}_{t=0} \right], \end{aligned}$$

since $c^{(0)}(0) = c(0) = 0$. Then by induction we infer that

$$\frac{d^l}{dt^l} \left\{ \text{ad}_{c_u(t)}^k (\dot{c}_u(t)) \right\}_{t=0} = 0 \quad \forall k \geq 1, \forall l \in [0, k],$$

which implies for any $l \geq k + 2 \geq 2$,

$$\frac{d^l}{dt^l} \left\{ \text{ad}_{c(t)}^{k+1} (\dot{c}(t)) \right\}_{t=0} = \sum_{r=k+1}^{l-1} \binom{l}{r} \left[c^{(l-r)}(0), \frac{d^r}{dt^r} \left\{ \text{ad}_{c(t)}^k (\dot{c}(t)) \right\}_{t=0} \right]. \quad (3.8)$$

We claim that

$$\frac{d^{k+r}}{dt^{k+r}} \left\{ \text{ad}_{c(t)}^k (\dot{c}(t)) \right\}_{t=0} \in V_1 \oplus \dots \oplus V_{k+r} \quad \forall k \geq 0, \forall r \geq 1, \quad (3.9)$$

which gives the desired result for $l = 0$ and $r \geq 1$. Let us prove it by induction. Taking $t = 0$ in (3.7) and its derivative gives

$$\dot{c}(0) = \sum_{i=1}^m h_i(0)e_i^1, \quad \ddot{c}(0) = \sum_{i=1}^m \dot{h}_i(0)e_i^1 \in V_1,$$

whose the second equality means that (3.9) is satisfied with $k = 0, r = 1$. Applying (3.8) with $l = k + 2$ yields

$$\frac{d^{k+2}}{dt^{k+2}} \left\{ \text{ad}_{c(t)}^{k+1} (\dot{c}(t)) \right\}_{t=0} = (k+2) \left[\dot{c}(0), \frac{d^{k+1}}{dt^{k+1}} \left\{ \text{ad}_{c(t)}^k (\dot{c}(t)) \right\}_{t=0} \right] \quad \forall k \geq 0.$$

We deduce easily that (3.9) holds for any pairs (k, r) with $k \geq 0$ and $r = 1$. Assume now that (3.9) holds for any pairs (k, r) with $k \geq 0$ and $r \leq q$ for some integer $q \geq 1$ and show how to deduce the result for the pairs $(k, q+1)$. Taking $q+1$ derivatives in (3.7) gives

$$\begin{aligned} c^{(q+2)}(0) &= \sum_{i=1}^m h_i^{(q+1)}(0)e_i^1 - \sum_{k=1}^{s-1} \frac{(-1)^k}{(k+1)!} \frac{d^{q+1}}{dt^{q+1}} \left\{ \text{ad}_{c(t)}^k (\dot{c}(t)) \right\}_{t=0} \\ &= \sum_{i=1}^m h_i^{(q+1)}(0)e_i^1 - \sum_{k=1}^q \frac{(-1)^k}{(k+1)!} \frac{d^{q+1}}{dt^{q+1}} \left\{ \text{ad}_{c(t)}^k (\dot{c}(t)) \right\}_{t=0} \\ &= \sum_{i=1}^m h_i^{(q+1)}(0)e_i^1 - \sum_{k=1}^q \frac{(-1)^k}{(k+1)!} \frac{d^{k+(q+1-k)}}{dt^{k+(q+1-k)}} \left\{ \text{ad}_{c(t)}^k (\dot{c}(t)) \right\}_{t=0}. \end{aligned}$$

Since $q+1-k \leq q$ for every $k \in [1, q]$, we infer that

$$c^{(q+2)}(0) = \frac{d^{q+1}}{dt^{q+1}} \left\{ \text{ad}_{c(t)}^0 (\dot{c}(t)) \right\}_{t=0} \in V_1 \oplus \cdots \oplus V_{q+1}.$$

Now applying (3.8) with $l = k+1+q+1$ and $k \geq 0$ yields

$$\begin{aligned} \frac{d^l}{dt^l} \left\{ \text{ad}_{c(t)}^{k+1} (\dot{c}(t)) \right\}_{t=0} &= \sum_{r=k+1}^{k+1+q} \binom{l}{r} \left[c^{(l-r)}(0), \frac{d^r}{dt^r} \left\{ \text{ad}_{c(t)}^k (\dot{c}(t)) \right\}_{t=0} \right] \\ &= \sum_{r=1}^{q+1} \binom{l}{k+r} \left[c^{(q+2-r)}(0), \frac{d^{k+r}}{dt^{k+r}} \left\{ \text{ad}_{c(t)}^k (\dot{c}(t)) \right\}_{t=0} \right] \end{aligned}$$

We conclude easily by induction on k . □

Let us finish the proof of Theorem 5. Thanks to a result by Agrachev [1], the set of smooth points is open and dense in \mathbb{G} . This implies that there are $x \in \mathbb{G}$ and an open (and bounded) neighborhood \mathcal{V} of x such that for every $y \in \mathcal{V}$, there is a unique minimizing geodesic $\gamma_y : [0, 1] \rightarrow \mathbb{G}$ from 0 to y . Moreover, this geodesic is not a singular point of the sub-Riemannian exponential map $\exp_0 : T_0^* \mathbb{G} = \mathfrak{g}^* \rightarrow \mathbb{G}$; in particular γ_y is the projection of a unique normal extremal. By analyticity, this implies that for every $t \in [0, 1]$ small enough and every $y \in \mathcal{V}$, there is a unique minimizing geodesic from 0 to $\gamma_y(t)$ which in addition is not a singular point of the SR exponential map (see [24]). Let us pull back everything in \mathfrak{g} . Define the map $\Psi : \mathbb{R}^n \rightarrow \mathfrak{g}$ by (we now denote c by c_h to stress the dependence of c upon h)

$$\Psi(h) := c_h(1) \quad \forall h \in \mathbb{R}^n.$$

By the above discussion, we have for every measurable set $A \subset \mathcal{V}$ and every $s \in [0, 1]$ small enough,

$$\mathcal{L}(A_1) = \int_{D_1} D(h) dh \quad \text{and} \quad \mathcal{L}(A_s) = \int_{D_s} D(h) dh = \int_{D_1} s^n D(sh) dh,$$

where D denotes the Jacobian determinant of Ψ (which is nonnegative). Therefore if a sub-Riemannian structure on \mathbb{G} makes it a measured metric space which is geodesic with negligible cut loci satisfying MCP(0, N), then for every measurable set $A \subset \mathbb{R}^n$ with $\Psi(A) \subset \mathcal{V}$, there holds

$$\int_A s^n D(sh) dh \geq s^N \int_A D(h) dh \quad \forall s \in [0, 1] \text{ small,}$$

which implies

$$D(sh_x) \geq s^{N-n} D(h_x) \quad \forall s \in [0, 1],$$

where $h_x \in \mathbb{R}^n$ is defined as $\Psi(h_x) = x$. Define the function $\tilde{\Psi} : [0, 1] \times \mathbb{R}^n \rightarrow \mathfrak{g}$ by

$$\tilde{\Psi}(s, h) = \Psi(sh) \quad \forall s \in [0, 1], \forall h \in \mathbb{R}^n.$$

It is smooth (it is indeed analytic) and satisfies

$$\det \left(\frac{\partial \tilde{\Psi}}{\partial h}(s, h_x) \right) \geq s^N \det \left(\frac{\partial \tilde{\Psi}}{\partial h}(1, h_x) \right) \quad \forall s \in [0, 1] \text{ small.} \quad (3.10)$$

Note that

$$\frac{d}{ds} \left\{ \det \left(\frac{\partial \tilde{\Psi}}{\partial h}(s, h_x) \right) \right\}_{s=0} = \sum_{i=1}^n \det \left(\left[\frac{\partial^2 \tilde{\Psi}}{\partial h \partial s}(0, h_x) \right]_i \right),$$

where $\left[\frac{\partial \tilde{\Psi}}{\partial h \partial s} (0, h_x) \right]_i$ is the Jacobian matrix

$$\left[\frac{\partial \tilde{\Psi}}{\partial h_1} (0, h_x), \dots, \frac{\partial \tilde{\Psi}}{\partial h_n} (0, h_x) \right]$$

whose the i -th column is replaced by

$$\frac{\partial^2 \tilde{\Psi}}{\partial h_i \partial s} (0, h_x) = \frac{\partial \dot{c}_h}{\partial h} (0).$$

More generally, the k -th derivative

$$\frac{d^k}{ds^k} \left\{ \det \left(\frac{\partial \tilde{\Psi}}{\partial h} (s, h_x) \right) \right\}_{s=0} \quad (3.11)$$

can be expressed as a sum of determinants of matrices of the form

$$\left[\frac{\partial^{1+\beta_1} \tilde{\Psi}}{\partial h \partial s^{\beta_1}} (0), \dots, \frac{\partial^{1+\beta_n} \tilde{\Psi}}{\partial h \partial s^{\beta_n}} (0) \right] \quad (3.12)$$

with β_1, \dots, β_n some integers verifying

$$\beta_1, \dots, \beta_n \geq 0 \quad \text{and} \quad \beta_1 + \dots + \beta_n \leq k.$$

By Lemma 13, we know that

$$\frac{\partial^2 \tilde{\Psi}}{\partial h \partial s} (0) = \frac{\partial \dot{c}}{\partial h} (0) \in V_1 \quad \text{and} \quad \frac{\partial^{1+l} \tilde{\Psi}}{\partial h \partial s^l} (0) = \frac{\partial c^{(l)}}{\partial h} (0) \in V_1 \oplus \dots \oplus V_{l-1} \quad \forall l \geq 2.$$

Then in order to be non-vanishing, the sum which gives the k -th derivative (3.11) has to contain a term of the form (3.12) with a set $\{\beta_1, \dots, \beta_n\}$ consisting of at least m_1 elements ≥ 1 and for every $k = 2, \dots, s$, m_k elements $\geq k + 1$. This gives the result.

4 Comments and open problems

4.1 On ideal Carnot groups

Recall that a totally nonholonomic distribution Δ on a smooth manifold M is called fat if, for every $x \in M$ and every section X of Δ with $X(x) \neq 0$, there holds

$$T_x M = \Delta(x) + [X, \Delta](x), \quad (4.1)$$

where

$$[X, \Delta](x) := \left\{ [X, Z](x) \mid Z \text{ section of } \Delta \right\}.$$

Any fat distribution does not admit non-trivial singular curve. As a consequence any fat Carnot group is ideal. Fat Carnot groups are Carnot group of step $s = 2$ such that

$$[V_1, v] = V_2 \quad \forall v \in V_1.$$

This is the case of Heisenberg groups. We refer the reader to [22, 24] for further details on fat distributions.

Let \mathbb{G} be a Carnot group whose first layer is equipped with a left-invariant metric. Using the same notations as in Section 2.3 and proceeding as in the proof of Proposition 9, singular curves can be characterized as follows (see [12]):

Proposition 14. *Let $\gamma \in W^{1,2}([0, T]; \mathbb{G})$ be an horizontal curve with $\gamma(0) = 0$ associated with a control $u^\gamma \in L^2([0, T]; \mathbb{R}^m)$ such that*

$$\dot{\gamma}(t) = \sum_{i=1}^m u_i^\gamma(t) X_i^1(\gamma(t)) \quad \text{a.e. } t \in [0, T].$$

Then γ is singular if and only if there is an non-vanishing absolutely continuous function

$$h = (h^1, \dots, h^s) : [0, T] \longrightarrow \mathbb{R}^{m_1} \times \mathbb{R}^{m_s}$$

satisfying

$$\begin{cases} \dot{h}^l(t) &= \sum_{k=1}^{m(l+1)} h_k^{l+1}(t) A_k^{1l} u^\gamma(t) \quad \forall l \in 1, \dots, s-1, \\ \dot{h}^s(t) &= 0, \end{cases} \quad \text{a.e. } t \in [0, T],$$

such that

$$h^1(t) = 0 \quad \forall t \in [0, T].$$

As a consequence, for every $\bar{h} = (\bar{h}^1, \dots, \bar{h}^s) \in \mathbb{R}^n \setminus \{0\}$ with $\bar{h}^1 = 0$ such that the linear mapping $\mathcal{S}_{\bar{h}} : \mathbb{R}^m \rightarrow \mathbb{R}^{n-m(s)}$ defined by

$$\mathcal{S}_{\bar{h}}(v) = \left(\left[\sum_{k=1}^{m(2)} \bar{h}_k^2 A_k^{11} \right] v, \dots, \left[\sum_{k=1}^{m(s)} \bar{h}_k^s A_k^{1(s-1)} \right] v \right)$$

is not injective, there is an horizontal curve $\gamma : [0, 1] \rightarrow \mathbb{G}$ associated with a constant control $u^\gamma \equiv \bar{u}$ (with $\bar{u} \in \text{Ker}(\mathcal{S}_{\bar{h}})$) which is singular. By Proposition 9 we check easily that such a curve is the projection of a normal extremal. Since short projections of

normal extremal are minimizing (see [24]), this shows that any Carnot group admitting $\bar{h} \in \mathbb{R}^n \setminus \{0\}$ with $\bar{h}^1 = 0$ such that $\mathcal{S}_{\bar{h}}$ is not injective is not ideal. For example, this is the case of Carnot groups of step 2 which are not fat or Carnot groups of step $s \geq 3$ with growth vector (m_1, \dots, m_s) (remember (2.4)) with $m_r < m_1$ for some $r \in \{2, \dots, s-1\}$.

4.2 Approximation of SR structures on Carnot groups

The Heisenberg group \mathbb{H}_1 equipped with its canonical sub-Riemannian metric is the sub-Riemannian structure $(\mathbb{R}^3, \Delta, g)$ where Δ is the totally nonholonomic rank 2 distribution spanned by the vector fields

$$X = \partial_x - \frac{y}{2}\partial_z \quad \text{and} \quad Y = \partial_y + \frac{x}{2}\partial_z,$$

and g is the metric making $\{X, Y\}$ an orthonormal family of vector fields. A Haar measure is given by the Lebesgue measure \mathcal{L}^3 . As in [15], let us introduce the one-parameter family of Riemannian metrics g_ϵ on \mathbb{R}^3 which are left-invariant by the Lie group structure and such that the family

$$\left\{ X, Y, \epsilon \frac{\partial}{\partial z} \right\}$$

is orthonormal. The Hamiltonian $H : \mathbb{R}^3 \times (\mathbb{R}^3)^* \rightarrow \mathbb{R}$ associated with this Riemannian metric is given by

$$H((x, y, z), (p_x, p_y, p_z)) = \frac{1}{2} (p_x - yp_z/2)^2 + \frac{1}{2} (p_y + xp_z/2)^2 + \frac{1}{2} \epsilon^2 p_z^2.$$

The Hamiltonian system is given by

$$\begin{cases} \dot{x} &= p_x - yp_z/2 \\ \dot{y} &= p_y + xp_z/2 \\ \dot{z} &= -(p_x - yp_z/2)y/2 + (p_y + xp_z/2)x/2 + \epsilon^2 p_z \end{cases} \quad (4.2)$$

and

$$\begin{cases} \dot{p}_x &= -(p_y + xp_z/2)p_z/2 \\ \dot{p}_y &= (p_x - yp_z/2)p_z/2 \\ \dot{p}_z &= 0. \end{cases} \quad (4.3)$$

The solution of (4.2)-(4.3) starting at $(0, \bar{p}) \in \mathbb{R}^3 \times (\mathbb{R}^3)^*$ is given by

$$\begin{cases} x(t) &= \frac{\bar{p}_y}{\bar{p}_z} (\cos(\bar{p}_z t) - 1) + \frac{\bar{p}_x}{\bar{p}_z} \sin(\bar{p}_z t) \\ y(t) &= -\frac{\bar{p}_x}{\bar{p}_z} (\cos(\bar{p}_z t) - 1) + \frac{\bar{p}_y}{\bar{p}_z} \sin(\bar{p}_z t) \\ z(t) &= \epsilon^2 \bar{p}_z t + \frac{\bar{p}_x^2 + \bar{p}_y^2}{2\bar{p}_z} \left(t - \frac{\sin(\bar{p}_z t)}{\bar{p}_z} \right) \end{cases} \quad (4.4)$$

Note that the solutions of (4.2)-(4.3) are invariant by rotation. For every $\theta \in \mathbb{R}$, denote by R_θ the rotation of angle θ with vertical axis. Then we have (here $\exp_0 : T^*\mathbb{R}^3 = \mathbb{R}^3 \times (\mathbb{R}^3)^* \rightarrow \mathbb{R}^3$ denotes the sub-Riemannian exponential mapping, see [24])

$$\exp_0(R_\theta(\bar{p})) = R_\theta(\exp_0(\bar{p})) \quad \forall \bar{p} \in (\mathbb{R}^3)^*.$$

Let us now work in cylindrical coordinates, we represent a vector \bar{p} as a triple (θ, ρ, p_z) and its image by \exp_0 as a triple (e_θ, e_ρ, e_z) in such a way that in this new set of coordinates we have (with $p_z \neq 0$)

$$\frac{\partial e_\theta}{\partial \theta} = 1, \quad \frac{\partial e_\rho}{\partial \theta} = 0, \quad \frac{\partial e_z}{\partial \theta} = 0$$

and

$$\begin{cases} e_\rho(\theta, \rho, p_z) &= \rho \left| \frac{\sin(p_z/2)}{p_z/2} \right| \\ e_z(\theta, \rho, p_z) &= \epsilon^2 p_z + \frac{\rho^2}{2p_z} \left(1 - \frac{\sin(p_z)}{p_z} \right). \end{cases}$$

Denoting by $\tilde{\text{exp}}_0$ the exponential mapping in this new set of coordinates, we have for every triple (θ, ρ, p_z) ,

$$\begin{aligned} \text{Jac}_{\theta, \rho, p_z} \tilde{\text{exp}}_0 &= \det \begin{pmatrix} \frac{\partial e_\rho}{\partial \rho} & \frac{\partial e_\rho}{\partial p_z} \\ \frac{\partial e_z}{\partial \rho} & \frac{\partial e_z}{\partial p_z} \end{pmatrix} \\ &= \epsilon^2 \frac{\sin(p_z/2)}{p_z/2} + \frac{2\rho^2}{p_z^3} \left(\sin(p_z/2) - (p_z/2) \cos(p_z/2) \right). \end{aligned}$$

Therefore, for every measurable set $A \subset \mathbb{R}^3$ with $0 < \mathcal{L}^3(A) < \infty$, we have (we denote by \tilde{A} the set A in our set of coordinates)

$$\mathcal{L}^3(A) = \int_{\tilde{A}_1} e_\rho de_\theta de_\rho de_z = \int_{\tilde{D}_1} \rho \left| \frac{\sin(p_z/2)}{p_z/2} \right| |\text{Jac}_{\theta, \rho, p_z} \tilde{\text{exp}}_0| d\theta d\rho dp_z,$$

and for every $s \in [0, 1]$,

$$\begin{aligned} \mathcal{L}^3(A_s) &= \int_{\tilde{A}_s} e_\rho de_\theta de_\rho de_z = \int_{\tilde{D}_s} \rho \left| \frac{\sin(p_z/2)}{p_z/2} \right| |\text{Jac}_{\theta, \rho, p_z} \tilde{\text{exp}}_0| d\theta d\rho dp_z \\ &= \int_{\tilde{D}_1} s^3 \rho \left| \frac{\sin(sp_z/2)}{sp_z/2} \right| |\text{Jac}_{\theta, s\rho, sp_z} \tilde{\text{exp}}_0| d\theta d\rho dp_z. \end{aligned}$$

Define the function $h, k : (0, \pi) \rightarrow \mathbb{R}$ by

$$h(\lambda) := \frac{\sin(\lambda)}{\lambda}, \quad k(\lambda) := \sin(\lambda) - \lambda \cos(\lambda) \quad \forall \lambda \in (0, \pi).$$

We check easily that the functions $\lambda \mapsto h(\lambda)$ and $\lambda \mapsto h(\lambda)k(\lambda)/\lambda^3$ are positive and decreasing on $(0, \pi)$. Then we have for any $s \in (0, 1), p_z \neq 0$,

$$\begin{aligned}
s^3 \rho h(sp_z/2) & \left[\epsilon^2 h(sp_z/2) + \frac{2\rho^2}{sp_z^3} k(sp_z/2) \right] \\
& = s^3 \rho \epsilon^2 h(sp_z/2)^2 + 2\rho^3 s^5 \left(\frac{h(sp_z/2)h(sp_z/2)}{s^3 p_z^3} \right) \\
& \geq s^3 \rho \epsilon^2 h(p_z/2)^2 + 2\rho^3 s^5 \left(\frac{h(p_z/2)h(p_z/2)}{p_z^3} \right) \\
& \geq s^5 \rho h(p_z/2) \left[\epsilon^2 h(p_z/2) + \frac{2\rho^2}{p_z^3} k(p_z/2) \right].
\end{aligned}$$

All in all, we get

$$\mathcal{L}^3(A_s) \geq s^5 \mathcal{L}^3(A) \quad \forall s \in [0, 1].$$

We leave the reader to check that the above discussion implies that the Heisenberg group H_1 equipped with the left-invariant Riemannian metric g_ϵ (with $\epsilon > 0$) satisfies MCP(0, 5). It also implies (taking $\epsilon = 0$), as checked by Juillet [15], that the Heisenberg group equipped with its canonical sub-Riemannian metric satisfies MCP(0, 5). This means that the measured metric space $(H_1, d_{SR}, \mathcal{L}^3)$ can be approximated (in Gromov-Hausdorff topology, see [27]) by a sequence of Riemannian measured metric spaces with the same curvature exponent. We do not know if such property holds for more general Carnot groups with finite curvature exponent. Let \mathbb{G} be a Carnot group whose first layer is equipped with a left-invariant metric g , assume that it is a geodesic space with negligible cut loci and that it satisfies MCP(0, N). Does there exists a sequence of left-invariant Riemannian metrics $\{g_\epsilon\}_{\epsilon>0}$ converging to g together with a sequence $\{N_\epsilon\}_{\epsilon>0}$ converging to N as $\epsilon \downarrow 0$ such that each Riemannian space (\mathbb{G}, g_ϵ) satisfies MCP(0, N_ϵ) ? Can we expect such a result for Carnot groups which admit left-invariant Riemannian metrics with positive Ricci curvatures on the orthogonal complement of the first layer (as for H_1 , see [15, 20]) ?

4.3 Step 2 Carnot groups

Recall that a totally nonholonomic distribution Δ on a smooth manifold M is called two-generating or of step 2 in M if

$$T_x M = \Delta(x) + [\Delta, \Delta](x) \quad \forall x \in M,$$

where $[\Delta, \Delta]$ is defined as

$$[\Delta, \Delta](x) := \left\{ [X, Y](x) \mid X, Y \text{ sections of } \Delta \right\}.$$

In [3] (see also [24]), Agrachev and Lee proved that any complete sub-Riemannian structure with a distribution of step 2 is Lipschitz, that is its sub-Riemannian distance is locally Lipschitz outside the diagonal in $M \times M$. The Lipschitzness of the sub-Riemannian distance outside the diagonal allows to recover assertions (ii)-(iv) of Proposition 8 for some closed set in M (which may be bigger than the one defined in (2.1) (see [1, 24])).

Proposition 15. *Let (Δ, g) be a Lipschitz sub-Riemannian structure on M . Then for every $x \in M$, there is a closed set $\mathcal{C}(x) \subset M$ of Lebesgue measure zero such that the pointed distance $d_{SR}(x, \cdot)$ is smooth on the open set $M \setminus \mathcal{C}(x)$ and for every $y \in M \setminus \mathcal{C}(x)$ there is only one minimizing geodesic between x and y and it is not singular.*

Therefore, any Carnot group \mathbb{G} of step 2 is Lipschitz and geodesic with negligible cut loci. By invariance by dilations and translations (as seen in the proof of Theorem 4), a 2 step Carnot group \mathbb{G} satisfies MCP(0, N) for some $N > 1$ if and only if there is $N > 0$ such that for every measurable set $A \subset B_{SR}(0, 1) \setminus B_{SR}(0, 1/2)$,

$$\text{vol}_{\mathbb{G}}(A_s) \geq s^N \text{vol}_{\mathbb{G}}(A) \quad \forall s \in [1/2, 1]. \quad (4.5)$$

The above proposition allows to show that (4.5) holds far from $\mathcal{C}(x)$ and indeed at least far from conjugate points. The validity of some MCP property depends on the behavior of the sub-Riemannian exponential mapping near conjugate points.

4.4 Other notions of synthetic Ricci curvature bounds

In the present paper, we have restricted our attention to the Ohta Measure Contraction Property. Many other notions of synthetic Ricci curvature bounds do exist, we refer the reader to [15] and [27] for further details. In particular, in [15, 16], Juillet checked that the canonical Sub-Riemannian on the Heisenberg group does not satisfy curvature dimension conditions in the sense of Lott-Villani [19] and Sturm [25, 26]. We may expect that more general Carnot groups do not satisfy those conditions.
